

2. The Problem: Modelling on Design Level

Aims

- Explain importance of architecture modelling
- Motivation for architecture language
- Engineering-like architecture modelling

Contents of Chapter 2

- 2.1. Architecture Paradigm
- 2.2. Errors, Changes, and Costs
- 2.3. Architecture Center of Development
- 2.4. “Architectures” in Literature
- ...

Architecture Paradigm - an Idealization

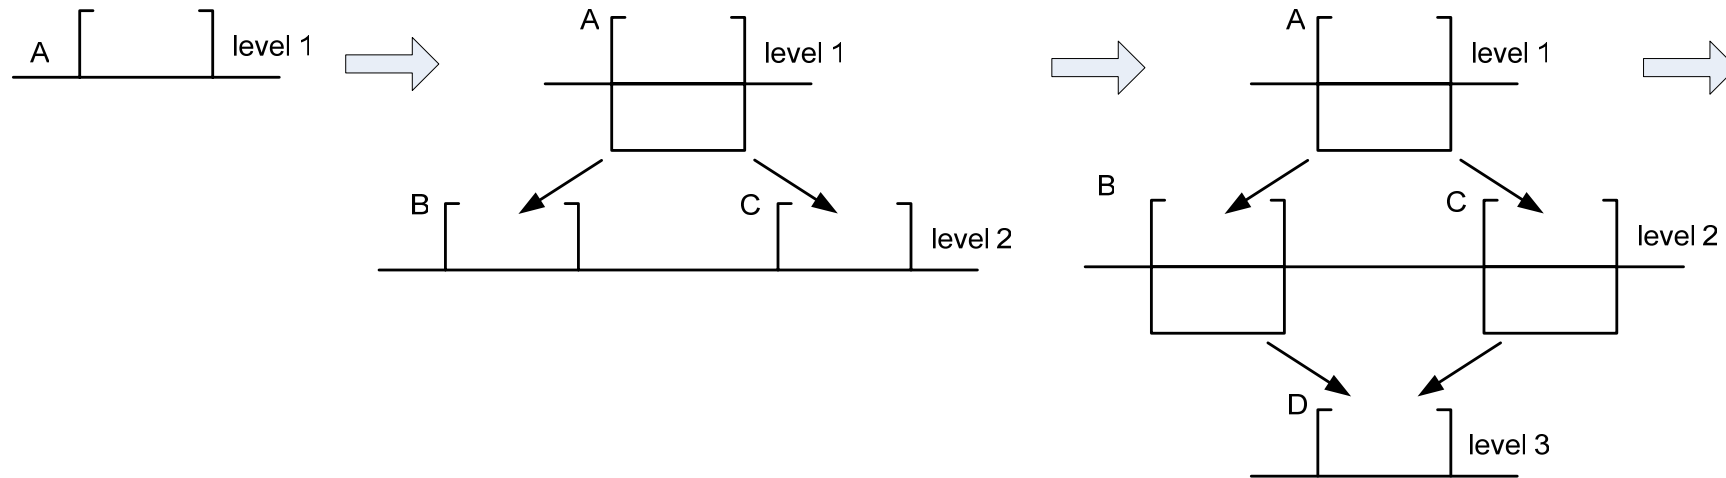

- Idealization:
 - » Design before implementation
 - » All components of all layers: only interfaces

- Problems:
 - » Identification of
 - ⇒ All layers
 - ⇒ All components
 } without realization

 - » Changes will happen:
 - ⇒ Components too complex
 - ⇒ trivial components

Alternative: Continuous Paradigm?

- ❑ Problems:
 - » No division of labor
 - » No architecture:
 - ⇒ No quality assurance before realization
 - ⇒ No reuse of components

Design Strategies

- ❑ Top-Down
- ❑ Bottom-Up
- ❑ Jo-Jo

Software Systems Are Wrong

N	p	$P = p^N$
10	0,99	0,9
10	0,9	0,35
100	0,99	0,37
100	0,9	0,000027

Correctness of a software system (Dijkstra)

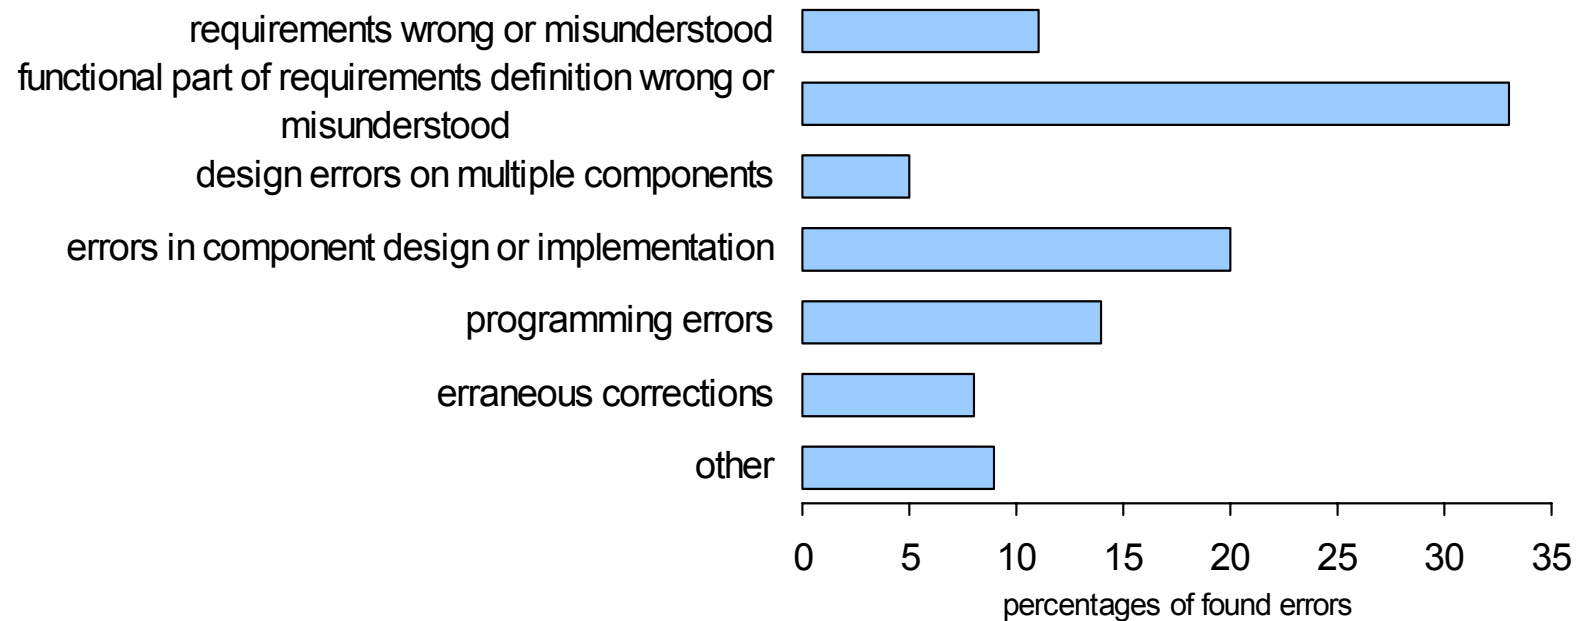

- ❑ Errors principal definition:
 - » Wrong: statically wrong, principally wrong
 - » Error: anywhere, anytime
- ❑ Errors practical definition:
 - » Time from error to error: acceptable
 - » error correction effort < benefit of system runs

Types of Errors

- ❑ Requirements:
 - » Requirements specification not reflecting needs
 - » Requirements specification incomplete, contradicting
- ❑ Architecture:
 - » Does not meet requirements
 - » Does not reflect SE quality measures: adaptability, portability, etc.
- ❑ Implementation:
 - » Component realization not consistent to design specification
 - » Realization wrong or inefficient
- ❑ Documentation:
 - » Analysis and design decisions not documented
 - » Documentation not consistent with technical system
- ❑ Project organization:
 - » Bad estimation, qualified developers unavailable, no clear responsibilities, no precise monitoring, no risk analysis

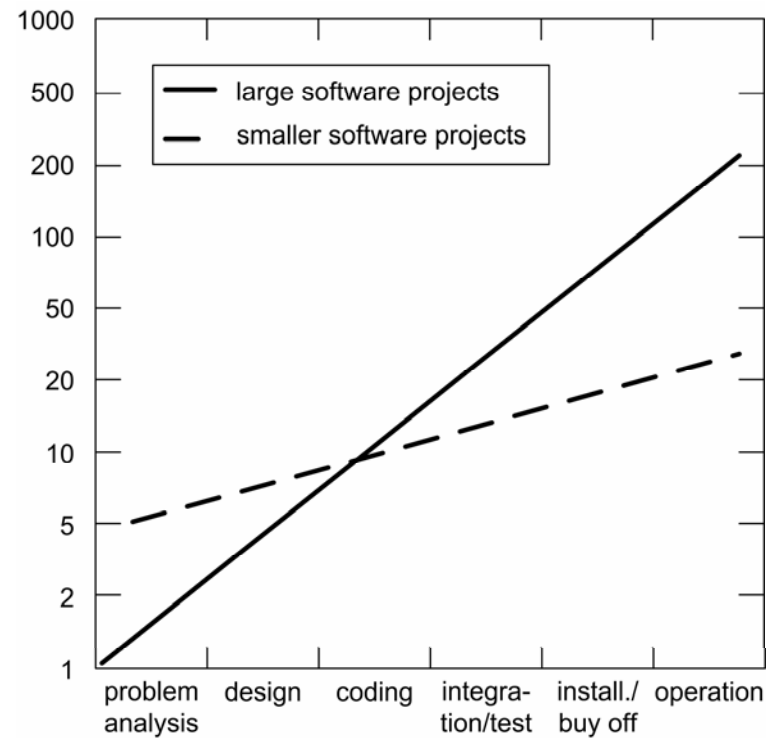

Design and Related Errors

- ❑ Minor effort for requirements engineering and design → many errors, high maintenance costs
- ❑ More than half of errors in early phases

Relative Costs of Errors

Relative costs

Errors detected in

- ❑ Relative and not absolute costs
- ❑ Error must have been made before detected
- ⇒ Avoid requirements and design errors

Conclusions

- More effort and competence
 - » More effort for early phases
 - » Suitable notations / methods necessary
 - » Experience and tools
- Better quality assurance
 - » Inspection of design results
 - » capability to evaluate demands for *
- Modifiable architectures
 - » Errors cause changes
 - » Changes are likely to happen
 - » Suitable architectures demand for *

Master Document “Architecture”

Thickness of circle corresponds to effort in development process

Thickness of edge: determination of results in dependent working area

⇒ development process mainly determined by design activity

- ❑ Architecture has to map requirements
- ❑ Architecture determines long-term quality of system
- ❑ One architecture can answer different requirements
- ❑ Organization of development
- ❑ Organization of change
- ❑ Design errors have influence

All Developers Have to Understand the Architecture

Purpose

- Graphical notation: for overview
- Textual notation: for design details, i.e. interface description

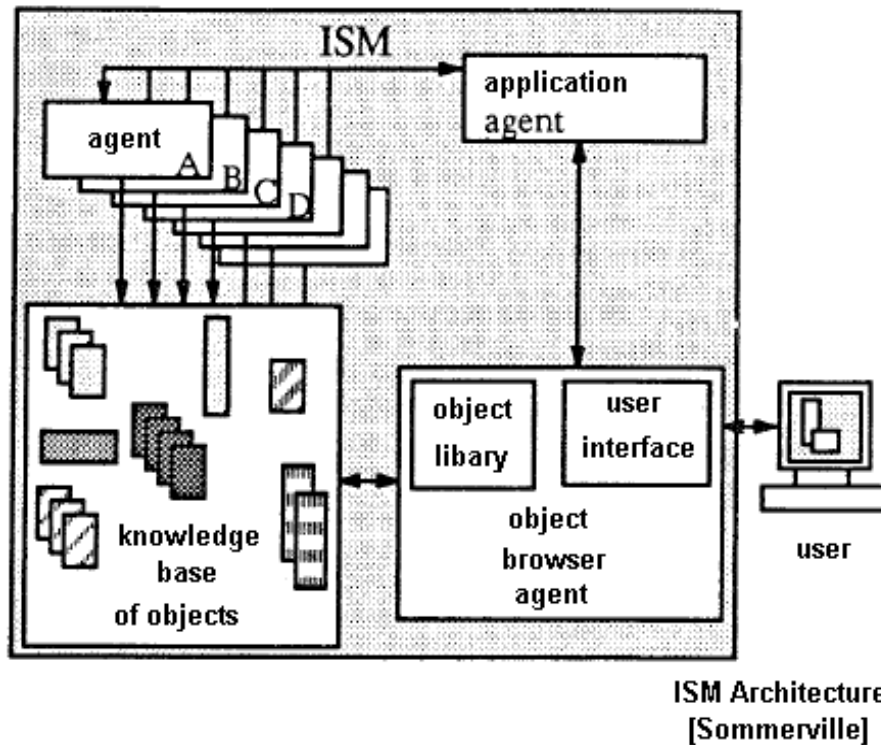

Both are a tremendous abstraction from source code

Architecture

- To estimate the effort of changes and to plan changes
- To carry out changes
- To study the structure of a system
- To identify reusable components, patterns, or standard solutions
- To define subprocesses in other working areas:
implementation, quality assurance, integration, and documentation

Architectures Are More Than Pictures

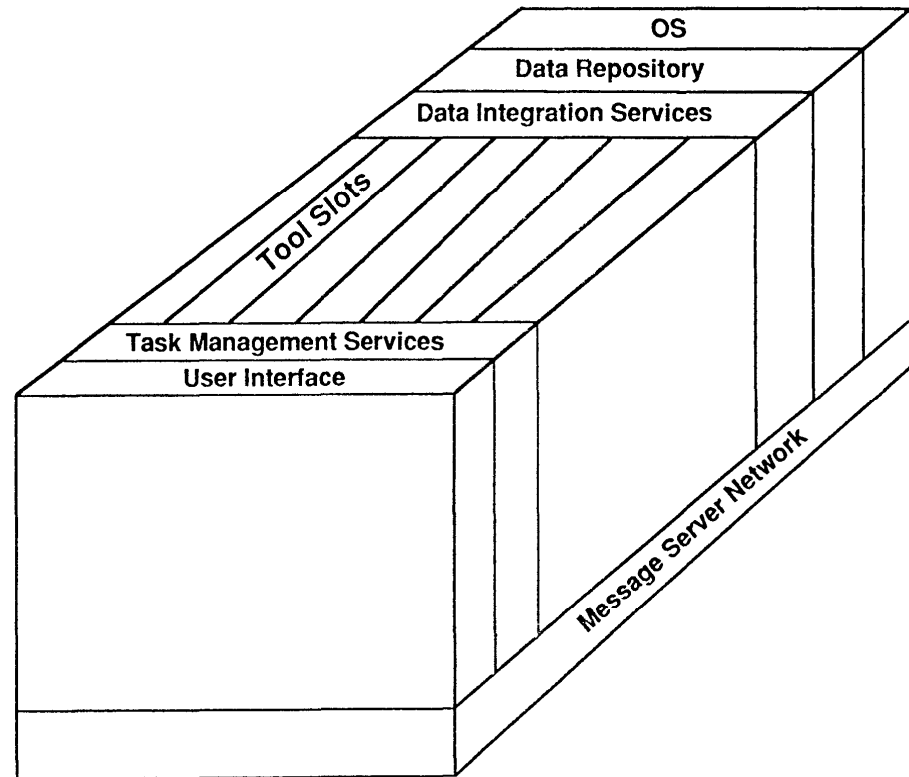

- What are architectures?

- "type" of units necessary
- User is not an architecture unit, but the interface to the user is
- Data objects are not units but a component to control these units
- Edges also need a clear static semantics

Boxes: any kind of entities
edges: any kind of relations

Another "Architecture": A Standard Built Plan ?

[ECMA]

- ❑ No integration: only all tools on the same basic layer working independently

Architectures in Business Administration

- ❑ Architecture = Schema e.g. EER
 - ❑ Translation into relational schema
 - ❑ Relational schema is a description used at runtime
- } Database system + description + operations are all means for organization, retrieval, or manipulation of data
- Application system using the database systems is not regarded

other modeling approaches: EER, function model, control model used for requirements engineering as well as design

Architectures in UML

- ❑ Different diagrams (denoted in different languages) describing different views of the system to be designed
 - ❑ Relations between diagram languages unclear, and if it were clear, it is still difficult to determine all relations
 - ❑ "Architecture" is a "refinement" of the requirements specification
 - ❑ Architecture: one result of a predefined process
- ⇒ There is no uniform built plan, no clear separation of requirements specification

Our Understanding of Architectures

- ❑ Built plan as result of the design subprocess
- ❑ Complete plan: all components, relations, and layers
- ❑ Consistent to requirements specification, but different from that
- ❑ Plan contains all relevant design decisions
- ❑ Abstraction compared to realized system (architecture paradigm)
- ❑ Independent from programming language, but see the restrictions of that language (e.g. no OO design if system is to be realized in C)
- ❑ The plan contains the structure of the system: that part OO, another modular, that layer abstracts from, ...
- ❑ The plan can be evaluated: portability, adaptability, ...
- ❑ Architectures are different: application domain, classes of systems, quality of design subprocess, used target system, etc.

Extended Understanding

- Static built plan

- But furthermore:
 - » Dynamic properties: denote typical execution paths
 - » Estimate future system properties: runtime behavior, deadlocks in concurrent systems, satisfiability of time constraints
 - » Describe properties of concurrent systems
 - » Describe distribution aspects
 - » Etc.

⇒ Architecture is not necessarily only a static plan
... an abstract plan

"One" Big Plan but Different Abstractions

- | | |
|---|--|
| □ Graphical overview | design (architecture) diagrams |
| □ Textual detailed descriptions | textual MIL language |
| □ Different subplans for essential parts | graphical & textual |
| □ Different further aspects <ul style="list-style-type: none">» Concurrency» Runtime behavior» Semantics of components» Distribution | "annotation" language |
| □ Design rationale as part of technical documentation | natural language explanation |
| □ "Specification" for use / purpose of modules / subsystems | natural language, decision tables, finite automata |

The Languages Have to Express

- ❑ Different "types" of components
- ❑ Different "types" of composition and usability relations
- ❑ Different granularity of parts: subarchitectures and subsystems
- ❑ Different further aspects: semantics, concurrency, distribution etc.
- ❑ Ideas behind
